Week 2: Identification, ignorability, and propensity scores

Molly Offer-Westort

Department of Political Science,
University of Chicago

Winter 2026

Recap MCAR: Missing Completely at Random

- Let Y_i and R_i be random variables with $\text{Supp}[R_i] = \{0, 1\}$.
- Let $Y_i^* = Y_i R_i + (-99)(1 - R_i)$.
- Y_i is MCAR if:
 - $Y_i \perp R_i$ (independence of outcome and response).
 - $\Pr[R_i = 1] > 0$ (nonzero probability of response).
- Note: implicitly, MCAR is with respect to *all* data, observed and unobserved. So, $R_i \perp (Y_i, X_i, \dots, Z_i, \dots)$.

Missingness wrt the full data

Definition (Full data, observed data, and response indicator)

Let U_i denote the *full-data* random vector for unit i , and let $R_i \in \{0, 1\}$ indicate whether the outcome component Y_i of U_i is observed. Write $U_i = (Y_i, X_i)$ where X_i collects all covariates measured (or conceptually present) for unit i . We observe

$$Y_i^* = Y_i R_i + (-99)(1 - R_i).$$

MCAR: Missing Completely at Random

Definition (Missing Completely at Random (MCAR))

Let $U_i = (Y_i, X_i)$ be the full-data vector and let $R_i \in \{0, 1\}$ be the response indicator. We say Y_i is *missing completely at random* if the following conditions hold:

1. $R_i \perp\!\!\!\perp U_i$ (missingness is independent of the full data),
2. $\Pr[R_i = 1] > 0$ (nonzero probability of response).

Equivalently, $R_i \perp\!\!\!\perp (Y_i, X_i)$ and $\Pr[R_i = 1] > 0$.

MAR: Missing at Random

Definition (Missing at Random (MAR))

Let Y_i and R_i be random variables and let $R_i \in \{0, 1\}$ be the response indicator. We observe $\mathbf{X}_i$ for all units (even when $R_i = 0$). We say Y_i is *missing at random conditional on $\mathbf{X}_i$* if the following conditions hold:

1. $R_i \perp\!\!\!\perp Y_i \mid \mathbf{X}_i$ (conditional independence of missingness and outcome),
2. $\exists \varepsilon > 0$ such that $\Pr[R_i = 1 \mid \mathbf{X}_i] > \varepsilon$ a.s. (positivity).

Proposition (MCAR implies MAR)

If $R_i \perp\!\!\!\perp (Y_i, \mathbf{X}_i)$, then $R_i \perp\!\!\!\perp Y_i \mid \mathbf{X}_i$. Therefore, MCAR implies MAR (with the same positivity condition).

Recap: missing data $\rightarrow$ potential outcomes

- Potential outcomes: $Y_i(1)$ and $Y_i(0)$.
- Observed outcome: $Y_i = Y_i(d) : D_i = d$.
- Only one potential outcome is observed; the other is missing.
- Identification requires assumptions about the assignment mechanism.

Recap: Manski and Nagin (1998) Utah juvenile court data

- How should judges sentence convicted juvenile offenders?
- Juvenile offenders in Utah may be assigned to residential or non-residential treatment programs.

Treatment (sentencing): $D = 1$ residential, $D = 0$ non-residential

Outcome (recidivism): $Y = 1$ recidivates, $Y = 0$ does not recidivate

Random assignment

- Let $Y_i(0)$, $Y_i(1)$, and D_i be random variables with $\text{Supp}[D_i] = \{0, 1\}$.
- Let $Y_i = Y_i(1)D_i + Y_i(0)(1 - D_i)$.
- D_i is **randomly assigned** if:
 - $(Y_i(0), Y_i(1)) \perp D_i$ (independence of potential outcomes and treatment).
 - $0 < \Pr[D_i = 1] < 1$ (positivity).
- Under this assumption, $E[\tau_i]$ is point identified.
- Aside: Does this independence need to hold for the full data?
- Implicitly: $R_i \perp\!\!\!\perp U_i^{pre}$ (missingness is independent of the full pre-intervention data)

ATE under random assignment

- If D_i is randomly assigned, then:

$$E[Y_i(1)] = E[Y_i \mid D_i = 1], \quad E[Y_i(0)] = E[Y_i \mid D_i = 0].$$

$$E[\tau_i] = E[Y_i \mid D_i = 1] - E[Y_i \mid D_i = 0].$$

Difference-in-means estimator

- Plug-in estimator under random assignment:

$$\hat{E}[\tau_i] = \frac{\sum_{i=1}^n Y_i D_i}{\sum_{i=1}^n D_i} - \frac{\sum_{i=1}^n Y_i (1 - D_i)}{\sum_{i=1}^n (1 - D_i)}.$$

Difference-in-means estimator (matrix form)

- Let

$$\mathbf{Y} = \begin{bmatrix} Y_1 \\ Y_2 \\ \vdots \\ Y_n \end{bmatrix}, \quad \mathbf{D} = \begin{bmatrix} D_1 \\ D_2 \\ \vdots \\ D_n \end{bmatrix}, \quad \mathbf{1} = \begin{bmatrix} 1 \\ 1 \\ \vdots \\ 1 \end{bmatrix}.$$

- Let $n_1 = \mathbf{1}^\top \mathbf{D}$ and $n_0 = \mathbf{1}^\top (\mathbf{1} - \mathbf{D})$. Mechanically,

$$n_1 = \begin{bmatrix} 1 & 1 & \cdots & 1 \end{bmatrix} \begin{bmatrix} D_1 \\ D_2 \\ \vdots \\ D_n \end{bmatrix} = \sum_{i=1}^n 1 D_i,$$

$$n_0 = \begin{bmatrix} 1 & 1 & \cdots & 1 \end{bmatrix} \begin{bmatrix} 1 - D_1 \\ 1 - D_2 \\ \vdots \\ 1 - D_n \end{bmatrix} = \sum_{i=1}^n 1(1 - D_i).$$

Difference-in-means estimator (matrix form)

$$\hat{E}[\tau_i] = \left(\frac{\mathbf{D}}{n_1} - \frac{1 - \mathbf{D}}{n_0} \right)^\top \mathbf{Y} \quad \left(\frac{\mathbf{D}}{n_1} - \frac{1 - \mathbf{D}}{n_0} \right) = \begin{bmatrix} \frac{D_1}{n_1} - \frac{1-D_1}{n_0} \\ \frac{D_2}{n_1} - \frac{1-D_2}{n_0} \\ \vdots \\ \frac{D_n}{n_1} - \frac{1-D_n}{n_0} \end{bmatrix}$$

$$\begin{aligned} \hat{E}[\tau_i] &= \left[\frac{D_1}{n_1} - \frac{1-D_1}{n_0}, \frac{D_2}{n_1} - \frac{1-D_2}{n_0}, \dots, \frac{D_n}{n_1} - \frac{1-D_n}{n_0} \right] \begin{bmatrix} Y_1 \\ Y_2 \\ \vdots \\ Y_n \end{bmatrix} \\ &= \sum_{i=1}^n \left(\frac{D_i}{n_1} - \frac{1-D_i}{n_0} \right) Y_i = \frac{1}{n_1} \sum_{i=1}^n D_i Y_i - \frac{1}{n_0} \sum_{i=1}^n (1-D_i) Y_i \\ &= \frac{\sum_{i=1}^n Y_i D_i}{\sum_{i=1}^n D_i} - \frac{\sum_{i=1}^n Y_i (1-D_i)}{\sum_{i=1}^n (1-D_i)}. \end{aligned}$$

Utah example: random assignment intuition

- Treat D_i as randomly assigned to residential vs. non-residential.
- Then treated and control groups have the same potential outcome distributions.
- Sample means within $D = 1$ and $D = 0$ identify $E[Y_i(1)]$ and $E[Y_i(0)]$.

Science table: random assignment

What would the difference in recidivism rates be if all juveniles were assigned to residential instead of non-residential treatment?

Target: $E[Y_i(1)] - E[Y_i(0)]$

i	$Y_i(0)$	$Y_i(1)$	D_i	Y_i
1	0	?	0	0
2	?	1	1	1
3	1	?	0	1
4	?	1	1	1
5	0	?	0	0
6	?	1	1	1
7	1	?	0	1
8	?	0	1	0
9	1	?	0	0
10	?	1	1	1

$$\hat{E}[Y_i(1)] = \frac{1+1+1+0+1}{5} = 0.8, \quad \hat{E}[Y_i(0)] = \frac{0+1+0+1+1}{5} = 0.6$$

$$\hat{E}[\tau_i] = 0.8 - 0.6 = 0.2$$

Strong ignorability

- Let $Y_i(0)$, $Y_i(1)$, and D_i be random variables with $\text{Supp}[D_i] = \{0, 1\}$.
- Let $Y_i = Y_i(1)D_i + Y_i(0)(1 - D_i)$.
- D_i is **strongly ignorable conditional on $\mathbf{X}_i$** if:
 - $(Y_i(0), Y_i(1)) \perp D_i \mid \mathbf{X}_i$ (conditional independence).
 - $\exists \varepsilon > 0$ such that $\varepsilon < \Pr[D_i = 1 \mid \mathbf{X}_i] < 1 - \varepsilon$ (positivity).
- Random assignment implies strong ignorability (with pre-treatment $\mathbf{X}_i$). Strong ignorability does *not* imply random assignment.

ATE under strong ignorability

- If D_i is strongly ignorable conditional on X_i , then:

$$E[\tau_i] = \sum_x E[Y_i \mid D_i = 1, X_i = x] \Pr[X_i = x] - \sum_x E[Y_i \mid D_i = 0, X_i = x] \Pr[X_i = x].$$

Conditional ATE under strong ignorability

- For any $x \in \text{Supp}[X_i]$:

$$E[\tau_i | X_i] = E[Y_i | D_i = 1, X_i] - E[Y_i | D_i = 0, X_i].$$

Post-stratification plug-in estimator under MAR

- Under MAR, $Y \perp R \mid X$, so:

$$E[Y] = \sum_{x \in \text{Supp}[X]} E[Y \mid R = 1, X = x] \Pr[X = x].$$

- Sample plug-in estimator:

$$\hat{E}[Y] = \sum_{x \in \text{Supp}[X]} \left(\frac{\sum_{i=1}^n Y_i^* \mathbb{1}\{R_i = 1\} \mathbb{1}\{X_i = x\}}{\sum_{i=1}^n \mathbb{1}\{R_i = 1\} \mathbb{1}\{X_i = x\}} \right) \left(\frac{\sum_{i=1}^n \mathbb{1}\{X_i = x\}}{n} \right).$$

Science table: ignorability (conditioning on X)

i	X_i	$Y_i(0)$	$Y_i(1)$	D_i	Y_i
1	A	0	?	0	0
2	A	?	1	1	1
3	B	1	?	0	1
4	B	?	1	1	1
5	A	0	?	0	0
6	A	?	1	1	1
7	B	1	?	0	1
8	B	?	0	1	0
9	A	1	?	0	0
10	B	?	1	1	1

$$\widehat{E}[Y_i \mid D_i = 1, X_i = A] = 1, \quad \widehat{E}[Y_i \mid D_i = 0, X_i = A] = 1/3$$

$$\widehat{E}[Y_i \mid D_i = 1, X_i = B] = 2/3, \quad \widehat{E}[Y_i \mid D_i = 0, X_i = B] = 1$$

$$\widehat{E}[Y_i(1)] = \frac{5}{10} \cdot 1 + \frac{5}{10} \cdot \frac{2}{3} = 0.833, \quad \widehat{E}[Y_i(0)] = \frac{5}{10} \cdot \frac{1}{3} + \frac{5}{10} \cdot 1 = 0.667$$

$$\widehat{E}[\tau_i] = 0.833 - 0.667 = 0.167$$

Response propensity function

- Suppose we observe $(R_i, \mathbf{X}_i)$ with $\text{Supp}[R_i] = \{0, 1\}$.

- The response propensity function is:

$$p_R(x) = \Pr[R_i = 1 \mid \mathbf{X}_i = x], \quad \forall x \in \text{Supp}[\mathbf{X}_i].$$

- The random variable $p_R(\mathbf{X}_i)$ is the (response) propensity score for unit i .
- It is the conditional probability of response given covariates.

MAR and the propensity score

- Let Y_i and R_i be random variables with $\text{Supp}[R_i] = \{0, 1\}$.
- Let $Y_i^* = Y_i R_i + (-99)(1 - R_i)$ and let $\mathbf{X}_i$ be a random vector.
- If Y_i is MAR conditional on $\mathbf{X}_i$, then:
 - $R_i \perp \mathbf{X}_i \mid p_R(\mathbf{X}_i)$ (balance conditional on $p_R(\mathbf{X}_i)$).
 - $Y_i \perp R_i \mid p_R(\mathbf{X}_i)$ (independence of outcome and response conditional on $p_R(\mathbf{X}_i)$).
 - $\exists \varepsilon > 0$ such that $\varepsilon < \Pr[R_i = 1 \mid p_R(\mathbf{X}_i)] < 1 - \varepsilon$.

Science table: MAR and the propensity score

i	$X_{[1]i}$	$X_{[2]i}$	$Y_i(0)$	R_i	$Y_i^*(0)$

$$\hat{p}_R(\mathbf{X}_i) = \frac{\sum_{i=1}^n R_i \mathbb{1}\{X_{[1]i}, X_{[2]i}\}}{\sum_{i=1}^n \mathbb{1}\{X_{[1]i}, X_{[2]i}\}}$$

$X_{[1]}$	$X_{[2]}$	n	$\hat{p}_R$
A	0	3	0.67
A	1	2	0.50
B	0	2	0.50
B	1	3	0.33

Estimation with the propensity score

$$\begin{aligned}\widehat{E}[Y_i(0)] &= \frac{3}{10}\widehat{E}[Y_i \mid R_i = 1, \widehat{p}_R(\mathbf{X}_i) = 0.67] + \\ &\quad \frac{4}{10}\widehat{E}[Y_i \mid R_i = 1, \widehat{p}_R(\mathbf{X}_i) = 0.50] + \\ &\quad \frac{3}{10}\widehat{E}[Y_i \mid R_i = 1, \widehat{p}_R(\mathbf{X}_i) = 0.33]\end{aligned}$$

$$\begin{aligned}\widehat{E}[Y_i \mid R_i = 1, \widehat{p}_R(\mathbf{X}_i) = 0.67] &= \frac{1}{2}, \quad \widehat{E}[Y_i \mid R_i = 1, \widehat{p}_R(\mathbf{X}_i) = 0.50] = \frac{1}{2}, \\ \widehat{E}[Y_i \mid R_i = 1, \widehat{p}_R(\mathbf{X}_i) = 0.33] &= 1 \\ &= \frac{3}{10} \cdot \frac{1}{2} + \frac{4}{10} \cdot \frac{1}{2} + \frac{3}{10} \cdot 1 = 0.65\end{aligned}$$

Treatment propensity function

- Let $Y_i(0)$, $Y_i(1)$, and D_i be random variables with $\text{Supp}[D_i] = \{0, 1\}$.
- Let $Y_i = Y_i(1)D_i + Y_i(0)(1 - D_i)$.
- The treatment propensity function is:

$$p_D(x) = \Pr[D_i = 1 \mid \mathbf{X}_i = x], \quad \forall x \in \text{Supp}[\mathbf{X}_i].$$

- The random variable $p_D(\mathbf{X}_i)$ is the (treatment) propensity score for unit i .

Strong ignorability and the propensity score

- Let $Y_i(0)$, $Y_i(1)$, and D_i be random variables with $\text{Supp}[D_i] = \{0, 1\}$.
- Let $Y_i = Y_i(1)D_i + Y_i(0)(1 - D_i)$ and $\tau_i = Y_i(1) - Y_i(0)$.
- If D_i is strongly ignorable conditional on $\mathbf{X}_i$, then:
 - $D_i \perp \mathbf{X}_i \mid p_D(\mathbf{X}_i)$ (balance conditional on $p_D(\mathbf{X}_i)$).
 - $(Y_i(0), Y_i(1)) \perp D_i \mid p_D(\mathbf{X}_i)$ (conditional independence).
 - $\exists \varepsilon > 0$ such that $\varepsilon < \Pr[D_i = 1 \mid p_D(\mathbf{X}_i)] < 1 - \varepsilon$.

Estimation with the treatment propensity score

$$\begin{aligned}\widehat{E}[Y_i(1)] &= \frac{3}{10} \widehat{E}[Y_i \mid D_i = 1, \widehat{p}_D(\mathbf{X}_i) = 0.33] + \\ &\quad \frac{4}{10} \widehat{E}[Y_i \mid D_i = 1, \widehat{p}_D(\mathbf{X}_i) = 0.50] + \\ &\quad \frac{3}{10} \widehat{E}[Y_i \mid D_i = 1, \widehat{p}_D(\mathbf{X}_i) = 0.67] \\ &= \frac{3}{10} \cdot 1 + \frac{2}{10} \cdot 1 + \frac{2}{10} \cdot 1 + \frac{3}{10} \cdot \frac{1}{2} = 0.85\end{aligned}$$

$$\begin{aligned}\widehat{E}[Y_i(0)] &= \frac{3}{10} \widehat{E}[Y_i \mid D_i = 0, \widehat{p}_D(\mathbf{X}_i) = 0.33] + \\ &\quad \frac{4}{10} \widehat{E}[Y_i \mid D_i = 0, \widehat{p}_D(\mathbf{X}_i) = 0.50] + \\ &\quad \frac{3}{10} \widehat{E}[Y_i \mid D_i = 0, \widehat{p}_D(\mathbf{X}_i) = 0.67] \\ &= \frac{3}{10} \cdot 0.5 + \frac{2}{10} \cdot 0 + \frac{2}{10} \cdot 1 + \frac{3}{10} \cdot 1 = 0.5\end{aligned}$$

$$\widehat{E}[\tau_i] = 0.85 - 0.5 = 0.35$$

Post-treatment variables

- Conditioning on post-treatment variables can break ignorability.
- A variable affected by treatment is not a valid adjustment set.
- DAG intuition: conditioning on descendants can open biasing paths.
- Preview: we will formalize this with DAGs in Weeks 3-4.

Post-treatment variables: why independence fails

- Example: $D \rightarrow M \rightarrow Y$ with M a post-treatment mediator.
- Even if $D \perp (Y(0), Y(1))$ (random assignment), $D \not\perp M$ because M is caused by D .
- Conditioning on M forces treated/control units to have the same mediator value, which mixes causal pathways and changes the estimand.

$$\Pr[M = 1 \mid D = 1] \neq \Pr[M = 1 \mid D = 0] \quad \Rightarrow \quad D \not\perp M.$$

Generalized potential outcomes model

- Allow multi-valued treatments: $D_i \in \text{Supp}[D_i]$.
- Generalized potential outcomes: $Y_i(d)$ for each $d \in \text{Supp}[D_i]$.
- Switching equation: $Y_i = \sum_{d \in \text{Supp}[D_i]} Y_i(d) \mathbb{1}\{D_i = d\}$.
- Preview: generalized propensity scores summarize $\Pr[D_i = d \mid X_i]$.

Average marginal causal effect

- If $Y_i(d)$ is differentiable with respect to d , the **average marginal causal effect** is:

$$\text{AMCE} = \text{E} \left[\frac{\partial \text{E}[Y_i(D_i) \mid D_i, X_i]}{\partial D_i} \right].$$

- Under conditional independence, the CEF is causal, so:

$$\text{AMCE} = \text{E} \left[\frac{\partial \text{E}[Y_i \mid D_i, X_i]}{\partial D_i} \right].$$

AMCE: local marginal effects

AMCE heterogeneity across covariates

Local slopes vary by X

Practice: AMCE with a non-uniform treatment

- Let $D \sim \text{Beta}(2, 2)$ on $(0, 1)$ and $X \sim \text{Bernoulli}(p)$, independent.
- Suppose the conditional mean function is

$$m(d, x) = \alpha + \beta d + \gamma d^2 + \eta x d.$$

- Compute the average marginal causal effect:

$$\text{AMCE} \equiv \text{E} \left[\frac{\partial}{\partial d} m(D, X) \right].$$

AMCE

Step 1: Differentiate $m(d, x)$ with respect to d .

$$m(d, x) = \alpha + \beta d + \gamma d^2 + \eta x d.$$

Differentiate term-by-term:

$$\frac{\partial}{\partial d} m(d, x) = 0 + \beta + 2\gamma d + \eta x = \beta + 2\gamma d + \eta x.$$

Step 2: Use linearity of expectation.

$$\text{AMCE} = \text{E}[\beta + 2\gamma D + \eta X] = \beta + 2\gamma \text{E}[D] + \eta \text{E}[X].$$

Since $X \sim \text{Bernoulli}(p)$,

$$\text{E}[X] = p.$$

Step 3: Compute the needed moment for $D \sim \text{Beta}(2, 2)$.

The screenshot shows the Wikipedia page for the Beta distribution. The page is titled "Beta distribution - Wikipedia" and is viewed in a browser window. The left sidebar contains a "Contents" section with links to "Definitions", "Properties", "Related distributions", "Statistical inference", and "Occurrence and applications". The main content area is titled "Definitions" and includes a section for the "Probability density function" (PDF). The PDF section explains that the PDF of the beta distribution, for $0 \leq x \leq 1$ or $0 < x < 1$, and shape parameters $\alpha, \beta > 0$, is a power function of the variable x and of its reflection $(1 - x)$ as follows:

$$f(x; \alpha, \beta) = \text{constant} \cdot x^{\alpha-1} (1-x)^{\beta-1}$$

$$= \frac{x^{\alpha-1} (1-x)^{\beta-1}}{\int_0^1 u^{\alpha-1} (1-u)^{\beta-1} du}$$

$$= \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha)\Gamma(\beta)} x^{\alpha-1} (1-x)^{\beta-1}$$

$$= \frac{1}{B(\alpha, \beta)} x^{\alpha-1} (1-x)^{\beta-1}$$

where $\Gamma(z)$ is the gamma function. The beta function, B , is a normalization constant to ensure that the total probability is 1. In the above equations

The right sidebar contains a table of properties for the Beta distribution:

Parameters	$\alpha > 0$ shape (real) $\beta > 0$ shape (real)
Support	$x \in [0, 1]$ or $x \in (0, 1)$
PDF	$\frac{x^{\alpha-1} (1-x)^{\beta-1}}{B(\alpha, \beta)}$ where $B(\alpha, \beta) = \frac{\Gamma(\alpha)\Gamma(\beta)}{\Gamma(\alpha + \beta)}$ and Γ is the Gamma function.
CDF	$I_x(\alpha, \beta)$ (the regularized incomplete beta function)
Mean	$E[X] = \frac{\alpha}{\alpha + \beta}$ $E[\ln X] = \psi(\alpha) - \psi(\alpha + \beta)$ $E[X \ln X] = \frac{\alpha}{\alpha + \beta} [\psi(\alpha + 1) - \psi(\alpha + \beta + 1)]$ (see section: Geometric mean) where ψ is the digamma function
Median	$I_{\frac{1}{2}}^{[-1]}(\alpha, \beta)$ (in general) $\approx \frac{\alpha - \frac{1}{3}}{\alpha + \beta - \frac{2}{3}}$ for $\alpha, \beta > 1$

Step 3: Compute the needed moment for $D \sim \text{Beta}(2, 2)$.
Compute $E[D]$. For the Beta distribution,

$$E[D] = \frac{\alpha}{\alpha + \beta} = \frac{2}{2 + 2} = \frac{1}{2}.$$

AMCE

Step 4: Substitute back into AMCE.

$$\text{AMCE} = \beta + 2\gamma\frac{1}{2} + \eta p = \beta + \gamma + \eta p.$$

$$\boxed{\text{AMCE} = \beta + \gamma + \eta p.}$$
